-----  
How to receive the same power level at a base station?

To receive the same power level at the base station, the mobiles those are closer to the base station should transmit less power than the mobiles which are far away from the mobile base station. In the figure given below, there are two mobile cells A and B. A is closer to the base station and B is far from the base station.

Why do base stations waste so much energy?

When there is little or no communication activity, base stations typically consume more than 80% of their peak power consumption, leading to significant energy waste. This energy waste not only increases operational costs, but also burdens the environment, which is contrary to global sustainability goals.

What happens if a mobile station is near a base station?

The signal from the mobile station that is near the base station may be significantly stronger than the signal from the mobile station that is far away, which can lead to the loss or significant degradation of the signal from the far mobile station. Reduced network bandwidth and coverage may follow from this.

Why is my base station not broadcasting?

The base station is not broadcasting. See Base station is not broadcasting below. Incorrect over-the-air baud rates between base station and rover. Connect to the roving receiver's radio and make sure that it has the same setting as the base station receiver. Mismatched channel or network number selection.

As a mobile node gets farther away from a base station, what are two actions that a base station could take to ensure that the loss probability of a transmitted frame does not increase?

This section describes some possible station setup and static measurement issues, possible causes, and how to solve them. Trimble recommends that you use the Trimble Access ...

In order to solve the near-far problem, interference cancellation is a technique that involves filtering out unwanted signals that interfere with a user's communication. This can be ...

Added bonus is that trains run power along the tracks so you've got a built-in power line to wherever your mines are. Trains are a bit power hungry though, so make sure you've ...

Added bonus is that trains run power along the tracks so you've got a built-in power line to wherever your mines are. Trains are a bit power hungry though, so make sure you've got a ...

To reduce the extra power consumption due to frequent sleep mode switching of base stations, a sleep mode switching decision algorithm is proposed. The algorithm reduces ...

In order to solve the near-far problem, interference cancellation is a technique that involves filtering out unwanted signals that interfere ...

When the power drops, it stops using hydrogen, so the hydrogen remains in the tanks. Adding a few fusion reactors or turning a few things off, brings the power back up.

The simulation and measurement results show that the proposed HT approach can achieve a near-ONF pattern and cover a ...

The simulation and measurement results show that the proposed HT approach can achieve a near-ONF pattern and cover a broad area of  $\pm 42^\circ$  on an eight-element linear array. ...

Your best shot is to build your coal power plant on site, and drag power poles all the way to your base. Much easier than dragging belts that you'll most likely upgrade later on

Power control is essentially needed to solve the near-far problem. The main idea to reduce the near-far problem, is to achieve the same power level received by all mobiles to the base station.
